Subject: ***Integrative Programming***
Activity: ***CONNECT PHP TO MYSQL***
Submitted To: ***Jeanahmae Carezo***

1. Overview (What I built)

- We built a small web application that uses PHP to connect to and interact with a MySQL database. The app lets a user add a name and email via an HTML form and then inserts that data into a users table in the database. It also includes a separate page to view the list of recently added users. The application logic, configuration, and presentation are kept in separate files.

2. Environment (What I used)

- We used XAMPP to provide the necessary local server environment, specifically Apache for serving the PHP files and MySQL for the database and we also used phpMyAdmin to run the initial SQL script to create the database and table. The code was written and organized using VS Code.

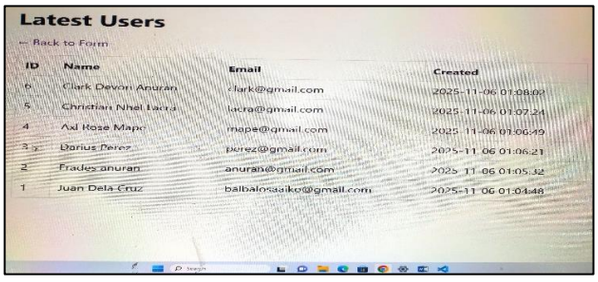
3. Database Setup (What SQL I ran)

- We ran the given SQL script in phpMyAdmin to create the database named sample_db and a table named users this created a table with columns for an auto-incrementing id, full_name, a unique email, and a created_at timestamp.

4. How the App Works (Simple Flow)

A. Screenshot B (Form):

B. Screenshot C (List):



5. What I Learned / Issues I Fixed

- I learned about how to make a small app using different files for the HTML form, CSS styles, and the PHP code that handles the database. And also we learn to use PHP to connect to MySQL so the app can collect user data (like Name and Email) and safely save it into a table , and then also show that data in a list view. The only real problem we ran into was that the first computer we used had a problem where XAMPP wasn't working right, so Apache and MySQL wouldn't start. We had to switch to another PC to finish the activity.

6. Files I Created

- **sql/create_db.sql:** Contains the SQL commands to create the sample_db database and the users table.

- **config.php:** Stores the database credentials.

- **index.html**: The user-facing HTML form for entering new user data.

- **style.css:** Provides minimal CSS styling and designing for readability.

- **insert.php:** Receives the form data and validates it, and also performs the safe database insertion.

- **list.php:** Connects to the database and retrieves the list of users, then displays them in an HTML table.
